

TREASURY REGISTER

The Cash Deployment Planner

One AI feature no one else has shipped this way.

A one-page pitch · Book dated 3 September 2026

THE PROBLEM

Every week, the same decision.

A treasurer has idle cash on Monday morning. Where does it go?

The decision is a five-way trade-off. Nobody does it on paper.

Yield	Concentration	Group headroom	Credit quality	Maturity ladder
--------------	----------------------	-----------------------	-----------------------	------------------------

In practice, the choice defaults to whoever's easiest — not whoever's best. Or the treasurer spends an hour in Excel every Monday and still gets it wrong.

› *The planner turns this into one click.*

One screen. Four bookable options.

Four candidates

Max yield · Diversified · Preserve headroom · Conservative

All bookable

Every one pre-checked against the six checks.

Trade-off visible

Bottom-right of the chart is the sweet spot. Haloed dot is the pick.

One-click Load

Chosen allocation drops into the ticket and re-runs the checks.

Everyone forecasts. Nobody places.

Every major treasury system has an AI story. Here is what they actually do.

Vendor	AI story	What it actually does
Kyriba	Copilot	Chat over your treasury data. No placement advice.
GTreasury	Clear	Cash forecasting. Predicts where cash will be.
HighRadius	Cash forecasting	AI-driven forecasts, receivables focus.
Coupa Treasury	Anomaly detection	Flags unusual payments. No placement flow.
SAP Treasury	Joule	Assistant across SAP modules. Generic.
Bloomberg	Terminal	Data and analytics. Not a workflow.
Treasury Register	Planner	Four ranked, bookable placements. One click to book.

› *Placement is the seat nobody else has taken.*

One card per option. Every figure explained

The card carries the whole plan: counterparty, rating, tenor, rate, principal, and where the placement would leave the counterparty afterwards. One Load button per allocation.

Four guardrails, one story.

The planner sits on top of the same six checks that gate every other deal on the book. Nothing about safety is new; the AI is layered on a control system that already works.

Pre-checked candidates

The four options are built by asking the six checks first. Anything that would fail is excluded before the list exists.

Re-checked on load

Clicking Load pipes the deal into the standard ticket. The six checks run again. The treasurer still signs.

Numbers are ours; prose is the model's

Every figure on every card is computed deterministically. The AI writes the trade-off label and picks the recommendation.

Model failure falls back cleanly

If the model is unreachable, the four candidates still appear and the recommendation defaults to the highest-yield option.

The seat, not just the feature.

The planner occupies a seat nobody else in the Oracle stack takes. EPM plans the business. Fusion moves the money. The Treasury Register is the layer between — the one that controls what may happen and, now, proposes what would be best.

Plan the business	Oracle EPM	Forecast cash flows across the enterprise.
Control what may happen	Treasury Register	The six checks. The planner. The queue.
Move the money	Oracle Fusion	Payments. Journals. Statements.

Kyriba, GTreasury and the rest live outside the Fusion stack. They can only integrate with a data hop. The planner runs on the same database as the control layer, and reads EPM's forecast as an input rather than trying to reproduce it.

› *EPM plans. Fusion moves. The register decides what happens in between.*

ONE LINE WORTH REMEMBERING

Everyone forecasts. Nobody places.

The Cash Deployment Planner is the only AI feature in the treasury stack that turns a five-way trade-off into four bookable options with the trade-off visible on the page.
