

Treasury Register

The control layer above Oracle Fusion

Before the demo - the problems we solve, how we complement Oracle, and what to look for

Fusion Practices - September 2026

Slide 1 of 14

The treasurer's day today

A blend of Oracle, a spreadsheet, a bank portal, a chat window, and a cup of coffee.

- **Idle cash sitting.** Money that could be earning yield sits uninvested because deciding where takes an hour of checks.
- **Manual six-check.** Rating, limit, group, tenor, concentration, permitted instrument - all read from a spreadsheet against a bank list before every deal.
- **Rating changes.** A downgrade lands by email; someone has to re-check every open position by hand.
- **Confirmation reconciliation.** Bank confirmation lands as a PDF or a SWIFT; someone matches fields by eye.
- **Audit trail.** Six systems, three spreadsheets. When the auditor asks who signed what against which limit on which day, it takes a week to reconstruct.

The register puts a single control surface in front of all of it. Every action is signed. Every figure comes from a check that was run and recorded.

Slide 2 of 14

Where Fusion already helps

Oracle Fusion is strong at the ledger, payments, and accounting hub. That is not where the decision problem lives.

Fusion component	What it does well
General Ledger + Accounting Hub	Books journals, posts to the ledger, drill-back to source. The system of record.
Cash Management	Holds the bank accounts, bank statement reconciliation, internal transfers.
Payments	Instructs the payment. Second approval before money moves - a critical control.
EPM (Cash Positioning + Forecasting)	Where the cash IS today and where it WILL be. Oracle shipped their own AI Agent for this in 26C.

We do not compete with any of this. We sit above it - and hand off to it.

Slide 3 of 14

Where Fusion leaves a decision-layer gap

Between EPM saying 'you have GBP 8m idle' and Fusion booking a journal, someone has to **decide**. Today that decision is manual.

- **No control surface for placement decisions.** Who to place with, how much, at what rate, for how long. Fusion has counterparties and limits; it does not run 'best placement under my policy' for you.
- **Six checks live outside the ledger.** Rating band, entity limit, group limit, tenor cap, concentration, permitted instrument. Each is read from a different system on the day.
- **Rating changes ripple silently.** A downgrade doesn't flag which of your live positions now sit outside policy. Someone has to walk the book.
- **Investment principles are policy, not code.** Buckets by rating, per-name cap, concentration ceiling - none of these live in a screen a treasurer can move a slider on.
- **Audit is retrospective, not built-in.** Every decision must be reconstructed. The register makes 'compliant when booked' a fact, not a claim.

This is the gap the Treasury Register fills.

Slide 4 of 14

Three lines to the story

EPM plans Where the money is, where it will be. Positioning, forecasting.

Register controls Which permitted counterparty and instrument, subject to six checks. Placement decision, gated.

Fusion moves Payment. Journal. Ledger. The money moves; the accounting drops. Second approval in Fusion.

Three companies could own each line. We own the middle - explicitly, deliberately, without over-reaching.

Slide 5 of 14

The six checks. One control moment.

Every path to book runs through these six. A deal that would fail any one is refused or requires an override reason.

Check	Refuses
Counterparty active	A counterparty that is suspended or withdrawn.
Instrument permitted	A GILT ticket against a counterparty that only trades DEPOSIT.
Entity limit	A new position that would put one name over its limit.
Group limit	Over-allocation across legal entities in the same ultimate parent.
Tenor band	A 24-month deal against a BBB+ name capped at 3 months.
Concentration	A placement that tips one group over the policy concentration ceiling.

The six checks are recorded on every deal - not recomputed, read back. That is what makes 'compliant when booked' a fact.

Slide 6 of 14

Investment principles - config, not code

Anil's Sep-8 principle: *"Nothing hardwired. Everything config-driven."* Buckets. Sliders. A treasurer sets them once per quarter.

- **Allocation buckets** by rating band: e.g. 50% AAA / 30% AA / 20% A / 0% BBB. Sliders sum to 100.
- **Risk floor**: the minimum rating the treasurer will invest in.
- **Per-name cap**: no single counterparty above N% of idle cash.
- **Group concentration cap**: no ultimate parent above N% of the portfolio.
- **Max tenor**: how long the treasurer is prepared to lock cash away.

The planner reads these on every run. Change a slider - reopen the planner - the numbers change. Not a marketing story; a live loop.

Slide 7 of 14

Blended plan - AI + policy in one screen

Not four side-by-side strategies to pick between. One **blended plan** that fits the principles, plus two alternatives for comparison.

Your blended plan - Fills every bucket the treasurer declared. Weighted rate, deployed, concentration - all named.

Higher yield - Shifts 20% down one rating band. Same buckets otherwise. Shows the yield lift for the credit-risk trade.

Tighter concentration - Same buckets, halves the per-name cap. Spreads across more names in each band.

Initiate all N at once button per plan. Every allocation runs the six checks in sequence; a blocked one lands in the queue.

Anil at Sep-8: "You wouldn't want to go either or. You want to do a blend." That's exactly what the planner returns.

Slide 8 of 14

AI a treasurer can trust

Every AI feature in the register follows the same pattern:

the model proposes; deterministic code disposes.

AI feature	Model proposes	Deterministic disposes
Advisory nightly ranker	Picks + writes a rationale	Rule-based fallback + validation catches invented figures
Confirmation parser	Extracts fields from unstructured text	Human review; six checks gate the ingest
Planner narrator	Labels candidates, picks one	Six-check-gated allocation set; the model never sees numbers
Performance insights	Drafts prose with a chosen lens (Yield / Diversification / Safety)	Every figure quoted comes from aggregates in the same response
Rating-change what-if	Classifies each deal: still passes / will breach / already breached	CheckEngine actually re-runs the six checks

A model that invents a figure is caught. A model that picks a candidate that would fail the six checks is caught. The fallback is always available.

Slide 9 of 14

Where the treasurer's time comes back

Every one of these was a manual step yesterday. Each is one click today.

~1 hr

Per placement decision

from spreadsheet + six manual checks to
Blended plan + Initiate

~30 s

Per confirmation

from PDF-to-fields by hand to **Confirmation**
parser with per-field review

~2 hr

Per rating action

from walk-the-book by hand to **What-if preview**
with per-deal impact

N clicks -> 1

Initiate a whole plan

one click sends every allocation in a blended plan through the six checks,
in sequence

Days -> minutes

Reconstruct an audit

the CheckRun on every deal captures the six checks as they stood, the
limit in force, and who signed

Slide 10 of 14

What the Register adds that isn't just faster

Speed matters. But some of the value is in what becomes **possible**, not just **quicker**.

- **Separation of duties enforced by the system.** A deal cannot be signed by the person who proposed it. The interface makes that visible before the click, not after.
- **Every AI action traced to a rule.** The advisory pick, the parser's field extraction, the planner's blend - all named against the deterministic rule that vets them.
- **Config-driven controls.** Investment principles, accounting-event catalogue, rating bands - editable by the treasurer, not by a developer.
- **Drill-back from GL to deal.** Accounting events published through the Connector preserve the source-transaction link; a GL balance drills to the deal that made it.
- **Realised income, honest.** Performance section reports what was recognised. Not projected. Not aspirational. Every figure ties to an accrual row.
- **Data-source labels on every screen.** Every rating chip names its provider. Every instrument names its source. A demo audience can ask 'where does that come from?' and see the answer on the screen.

Slide 11 of 14

The Treasury Register Connector - our IP, first-party

From Anil's Sep-8 feedback: "We should not be using Oracle Integration Cloud. We should build a connector in the Treasury management tool - our own Data Migration platform."

Route	How it worked	How it works now
Accounting events -> Fusion	Oracle Integration Cloud + ERP Cloud Adapter (extra Oracle PaaS SKU)	Treasury Register Connector - built into the app, no additional SKU
Bank connectivity	OIC or a third-party middleware	Treasury Register Connector - Bank-direct API adapter
EPM integration	OIC + Essbase bridge	Treasury Register Connector - EPM adapter
Custom endpoints	Bespoke integration project each time	Treasury Register Connector - one Custom REST adapter, config-driven

The Connector goes with the Register. Reusable across every Fusion Practices product. One fewer thing the client has to buy from Oracle to make this work.

Slide 12 of 14

What today's demo will walk through

Ten minutes. In this order, so the story lands cleanly:

- 1. Sign in. The book.** Nine counterparties across four rating bands. Every one shows its rating provider and its ISINs.
- 2. Investment principles.** Move a bucket slider. Save.
- 3. Deploy idle cash.** Blended plan fills the buckets. Two alternatives sit alongside. Initiate all N at once - one click.
- 4. Deal blotter.** Open a deal. Lifecycle timeline with the accounting-event badges - -> Fusion GL where relevant.
- 5. Performance.** AI insights across three lenses. Type in front of the audience. Projection card for 3/6/12 months.
- 6. Control -> Accounting events.** Destination dropdown. Treasury Register Connector, first-party. Toggle a stage; reopen the deal - the badge is there.
- 7. Reset. Nightly job.** Reset takes a second. Nightly job accrues, journals, and runs the advisory in front of the audience.

Nothing on screen is a mock. Every figure is computed live. Every source label names a real endpoint.

Slide 13 of 14

Prototype today. Path to production.

Rough order for the first working slice - 8 to 12 weeks:

1. Wire the Treasury Register Connector to the customer's Oracle Fusion pod (or EBS)
2. Register the Register as an AHCS source system; define event classes (Deals, Settlements, Accruals) and accounting rules
3. Wire the four lifecycle events (execute, settle, accrue, mature) to the destination through the Connector
4. Wire cashBankAccountTransfers for internal transfers
5. BICC extract on 15-minute cadence for bank balances into the Register
6. Rate provider contract (Bloomberg B-PIPE or LSEG Real-Time) for FX indicative pre-fill
7. Deposit rates: negotiated-rate memory in the Register; treasurer overrides on ticket

What's out of scope for the first slice: bank statement reconciliation (BICC/FBDI phase 2), cash position/forecast (EPM territory), firm-rate booking via a bank RFQ API (later phase, needs bank-side contract).

Slide 14 of 14

The ask

Watch the demo through the client's eyes. As we walk, tell me:

- Where does the story land - what's the sentence you'd repeat to a treasurer?
- What would a treasury-savvy sceptic push back on?
- Which screen deserves more polish before the client sees it?
- Is there a workflow we should demo that we're not?

Everything after the demo is a follow-up. This one call is where we get the story right.
